INSPECT UAR_DATA TALLYING COUNTER FOR CHARACTERS BEFORE INITIAL FIELD_VALUE.
If counter is less than uar_data_max_length
                                                                                                                                                                                                                                                                                                                                                                                                                               * To be valid, FIELD_VALUE must occur in the string UAR_DATA.
* This INSPECT statement sets COUNTER to the number of characters preceding
* FIELD_VALUE; thus, COUNTER will be 0 if the first character in UAR_DATA
* matched and UAR_DATA_LENGTH if the character is not found.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ILLEGAL_VALUE_MSG

## Chapter 6. Programming FMS Applications in VAX-11 FORTRAN

The FMS Form Driver processes all Form Driver calls according to VAX-11 standards and languagespecific rules. These rules define how arguments are passed to the Form Driver and how values are returned to your program. Language-specific information is briefly presented in this manual. For more detail, refer to the VAX-11 FORTRAN document set.

Your VAX-11 FORTRAN application program must comply with the requirements of the VAX-11 FORTRAN FMS interface. Topics discussed in this chapter include:

- Form Driver Routines
  - Invoking Form Driver Routines as Subroutines
  - Accessing Form Driver Status Codes as Functions
- Argument Passing in FMS
- Null Arguments
- FMS Data Types
  - Character Strings
  - Longword Binary Integers
  - Word Binary Integers
- Non-FMS Data Types
- One-Dimensional Arrays
- Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area
- Precautions for Using FMS
- Data Conversion
- Sample Application Program in VAX-11 FORTRAN

A sample program written in FORTRAN (SAMPFOR.FOR) appears at the end of this chapter. Following the code for SAMPFOR.FOR are Form Driver definition files created for SAMPFOR.FOR. Command file information needed to build the Sample Application program is in Section 6.10.2.

Examples from the Sample Application are used throughout the text to illustrate language issues. Where appropriate examples from SAMPFOR.FOR do not exist, other examples are provided.

## 6.1. Form Driver Routines

You can call any FMS routine as a subroutine or as a function. Syntax follows standard VAX-11 FORTRAN requirements.

#### 6.1.1. Invoking Form Driver Routines as Subroutines

You use the procedure call statement to invoke an FMS Form Driver routine. For example:

CALL FDV\$WAIT ()

Calls the Form Driver routine FDV\$WAIT and passes no arguments.

CALL FDV\$GET (OPTION, TERMINATOR, 'OPTION')

Calls the Form Driver routine FDV\$GET and passes three arguments.

See Appendix A for a complete list of Form Driver calls. The calling sequence for each Form Driver routine, data access codes, data types, and passing mechanisms are presented in language-independent notation as specified by the VAX-11 Procedure Calling and Condition Handling Standard. For further detail about the VAX-11 Procedure Calling and Condition Handling Standard, refer to the *VAX-11 Run-Time Library Reference Manual*.

# 6.1.2. Accessing Form Driver Status Codes as Functions

An FMS status code is returned to the calling program at the completion of all Form Driver calls. To receive the returned status code from a Form Driver routine, you activate the routine with a function reference rather than with a call statement. Note that this returns a standard VMS status code. For portability, other status mechanisms can also be used. For more information, see the *VAX-11 FMS Form Driver Reference Manual*, Chapter 2.

Before you reference a status\_return function, you declare its data type to be INTEGER\*4. The following statements declare and call FDV\$GET as an FMS function:

```
INTEGER*4 FDV$GET
INTEGER*4 RETURN_STATUS
RETURN STATUS = FDV$GET (OPTION, TERMINATOR, 'OPTION')
```

Alternatively, you can implicitly declare the data type of all FMS function names, using the IMPLICIT statement. The declaration IMPLICIT INTEGER\*4 F declares the data type of all the Form Driver subroutines to be INTEGER\*4 since all FMS-related names begin with F. Note that you cannot use this method if you are using the IMPLICIT NONE statement to ensure explicit declaration of all names in your program.

## 6.2. Argument Passing in FMS

The argument passing mechanism refers to the way in which data is passed to a called routine. The VAX-11 Procedure Calling Standard has three methods for passing arguments:

- By reference
- By descriptor
- By value

FMS routines, however, expect arguments to be passed only by reference and by descriptor.

**By reference** specifies that the storage location of the argument is passed to the routine. FMS expects integers to be passed by reference, which is also the FORTRAN default passing mechanism for integers.

**By descriptor** specifies that the address of a descriptor data structure is passed to the routine. FMS expects character strings and integer arrays to be passed by descriptor, which is the FORTRAN default passing mechanism for character strings (but not integer arrays).

Integer arrays require special treatment. Although the FORTRAN default passing mechanism for integer arrays is by reference, FMS has built-in functions for passing arguments when you wish to override FORTRAN default mechanisms. In this case, you can use the %DESCR function to force the argument list entry to use the descriptor mechanism. For example:

```
INTEGER*4 WORKSPACE (3)
CALL FDV$AWKSP (%DESCR(WORKSPACE), 2000)
```

### 6.3. Null Arguments

When the call syntax includes optional arguments and you do not wish to specify all of the information, you can use null arguments. Any optional argument can be omitted to simplify your program. A comma functions as a placeholder for each null argument. Optional arguments to the right of the last specified argument can simply be omitted from the call. In the following example, the FDV \$GETAL call passes only the field terminator value:

```
CALL FDV$GETAL (, FLDTRM)
```

## 6.4. FMS Data Types

#### 6.4.1. Character Strings

The character string is one of the general data types used by FMS. For example, the FDV\$GET call passes the character strings for field value (OPTION) and field name ('OPTION'):

```
CALL FDV$GET (OPTION, TERMINATOR, 'OPTION')
```

You must be certain that your strings are initially declared to be long enough to accommodate your FMS data. One option is to declare your fixedlength strings to be the exact length of the FMS data to be returned. You can use the FMS/DESCRIPTION/DECLARATIONS command to get the length of the strings.

Alternatively, a single string variable can be used in different FMS calls to transfer data to or from several forms and fields. You must declare the string variable to be at least as large as the longest field value string that will be returned to your program. You can use the FDV\$RETLE call to return the length of the valid portion of the field value in the string variable. This length can then be used when referencing the data that has been entered in the field. For example:

```
CHARACTER*100 ACCOUNT
.
.
.
CALL FDV$GET (ACCOUNT, TERMINATOR, 'FIELD')
CALL FDV$RETLE (LENGTHFIELD, 'FIELD')
.
.
```

```
WRITE (10,*) ACCOUNT(:LENGTHFIELD)
```

After the execution of the FDV\$RETLE call, LENGTHFIELD is equal to the length of the field named 'FIELD.' It is also equal to the valid portion of the string that is defined by the string descriptor ACCOUNT. LENGTH FIELD can now be used to reference the data that was entered in the field named 'FIELD', and that is now in the variable ACCOUNT. If you do not use the substring specifier (:LENGTHFIELD) when referencing ACCOUNT, you will reference the entire variable, including any blanks used by the Form Driver to pad the string.

A useful application of the FDV\$RETLE call is in general purpose user action routines.

#### 6.4.2. Longword Binary Integers

The longword binary integer is another general data type used by FMS. For example, the FDV \$ATERM call passes the longword value for terminal control area (12) and logical I/O channel number (2):

CALL FDV\$ATERM (%DESCR TCA),12,2)

Numeric arguments must be longword binary integers (INTEGER\*4). If you pass other numeric types to the Form Driver, the calls do not work properly. An exception is the FDV\$DFKBD call (see next section).

Note that you can declare numeric arguments to be INTEGER because the VAX default is INTEGER\*4. This will increase the compatibility of your program with PDP-11s, which have a default of INTEGER\*2.

#### 6.4.3. Word Binary Integers

The defkbd argument is a word integer array passed when the FDV\$DFKBD routine is called. FMS expects arrays to be passed by descrip tor.

#### 6.5. Non-FMS Data Types

FORTRAN data types that are not recognized by FMS can be used in your FORTRAN application program provided they are not passed to the Form Driver.

## 6.6. One-Dimensional Arrays

One-dimensional arrays are structures that can be used in FMS for the following arguments:

- tca (terminal control area)
- wksp (workspace)
- mloc (memory location)
- defkbd (define keyboard)

You must provide FMS with storage space for these arguments. You can do that by defining them to be:
- INTEGER\*4 arrays or character strings for tca, wksp, and mloc
- word integer arrays for defkbd

С

In the Sample Application program, the tca, wksp, and mloc arguments are passed to several Form Driver routines. These arguments are defined as integer array variables. The following declarations establish names and storage for the integer array variables WORKSPACE, CHECKWKSP, TCA, and MENU\_FORM:

Data definitions INTEGER WORKSPACE (3), !General workspace 1 CHECKWKSP (3), !Check workspace 2 TCA (3), !Terminal Control Area 3 MENU\_FORM (500), !Storage for memory-resident form

You may alternatively declare these variables to be character strings in your own application program. You could then take advantage of FORTRAN's default passing mechanism for character strings (by descriptor). This would avoid the need to use %DESC to force the descriptor mechanism for passing integer arrays. Furthermore, you could then declare the actual storage area of character strings in bytes. The following statements declare and allocate space to the character strings WORKSPACE, CHECKWKSP, and TCA:

```
CHARACTER*12 WORKSPACE
CHARACTER*12 CHECKWKSP
CHARACTER*12 TCA
```

## 6.7. Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area

The FMS workspace, terminal control area, and run-time memory-resident form area variables are character strings or longword integer arrays. These variables should be placed in a common storage area of your program. Note that this is not done in the Sample Application program. The sample program's structure protects the workspaces, terminal control areas, and runtime memory-resident form areas implicitly.

The Form Driver needs 12 bytes to associate user information about each workspace and terminal control area. The allocation for a run-time memory-resident form area must be the size of the form. The space for all of these variables is allocated by your application program. Note that FMS uses *only* 12 bytes of space for the workspace and terminal control area allocation. Any allocation greater than 12 bytes is wasted. You declare your workspace, terminal control area, and run-time memory-resident form area only once. FMS remembers their addresses after the addresses have been initially passed to the Form Driver.

For each workspace, the Form Driver also allocates an additional amount of storage space based on your estimate of the amount of memory needed to store your largest form. If your estimate is too small, the Form Driver allocates more space automatically, but performance may be affected. An adequate estimate results in more efficient operation of the Form Driver. You can use the FMS/ DIRECTORY/FULL command to find out how much space to allocate.

In the following example from the Sample Application program, workspace is allocated and the FDV\$AWKSP routine is called. When the FDV\$AWKSP routine is called, the first argument

(WORKSPACE) specifies the area of memory to be used for your workspace. The second argument specifies an estimate of the workspace size that you will need to display the largest form in your application.

```
C Data definitions

INTEGER WORKSPACE (3) !General workspace

1 CHECKWKSP (3) !Check workspace

CALL FDV$AWKSP (%DESCR(CHECKWKSP), 2000)

CALL FDV$AWKSP (%DESCR(WORKSPACE), 2000)
```

## 6.8. Precautions for Using FMS

#### 6.8.1. Memory Areas Used Exclusively by FMS

The locations for terminal control area, workspace, and run-time memoryresident form area are used exclusively by FMS. The terminal control area and workspace are attached with the FDV\$ATERM and FDV\$AWKSP calls and remain allocated until the FDV\$DTERM and FDV\$DWKSP calls are issued or until the program ends. The run-time memory-resident form area, used in the FDV\$READ call, remains allocated until the FDV\$DEL call is issued or until the program ends. You never touch the terminal control areas, workspaces, or run-time memory-resident form areas in your program except to pass their addresses to the Form Driver.

### 6.8.2. Why You Should Use the COMMON Attribute

Parameters to the following Form Driver routines should be used with caution:

FDV\$ATERM	Attach terminal
FDV\$AWKSP	Attach form workspace
FDV\$READ	Read form into memory
FDV\$SSRV	Specify status reporting variables

For example, once an FDV\$SSRV call is issued, the program variables that contain the FMS status and RMS status become volatile and can change at any call point. As a general rule, you should place the status reporting variables in COMMON.

In cases where you need both the FMS and RMS statuses, the FDV\$STAT routine can be used. Note that only the FDV\$STAT and FDV\$SSRV calls provide RMS status. With the FDV\$STAT routine, you do not have to worry about volatility.

The locations for terminal control area, workspace, run-time memory-resident form area, and status reporting variables must all continue to exist while the Form Driver is using them. They must remain allocated until the terminal control area and workspace are detached, until forms in memory location are deleted, and until the status reporting variables are no longer used. The variables can be protected by placing them in a common storage area; otherwise, the compiler might place them in dynamic storage or reuse their storage area.

## 6.9. Data Conversion

FMS uses only ASCII character strings to display data. All information displayed on the terminal screen, and all information received from the terminal operator, is represented as ASCII field values. Any manipulation of numeric data requires conversion of ASCII character strings to numeric data,

and conversion of numeric data back to ASCII character strings. In the following discussion of conversion routines, you should assume that the receiving data type can support the largest number that is likely to be generated.

In the Sample Application, the following steps are taken to get a new ac count balance after writing a check.

```
CALL FDV$RET (RI_AMTPAY, 'AMTPAY')
READ (RI_AMTPAY, '(I6)')
AMTPAY BALANCE = BALANCE - AMTPAY
TOTPAY = TOTPAY + AMTPAY
WRITE (RI_BALANCE, '(I6)') BALANCE
CALL FDV$PUT (RI_BALANCE, BALANCE')
```

In this example, the FORTRAN internal file READ converts the character variable RI\_AMTPAY to the integer variable AMTPAY according to the format specification of 16. The integer value of the variable AMTPAY is subtracted from the integer value of the variable BALANCE to produce a new value for BALANCE. When converting ASCII to numeric, your application is assured a successful conversion if the field on the form was defined as numeric. This eliminates the need for an "ERR =" clause on the READ statement.

After the data operations have been completed, the FORTRAN internal file WRITE converts the integer variable BALANCE to a character expression RI\_BALANCE. The value for the balance is displayed in the right-justified field 'BALANCE'. The rightmost digit from the program is displayed in the field's rightmost character position. The remaining digits of the character expression are placed to the left of the rightmost digit. If output is longer than the field, FMS truncates on the left. The Form Driver displays a data length error message (FDV\$\_DLN) only if you have set FMS Debug mode.

For other data conversion options, see the general conversion routines in the VAX-11 Run-Time Library Reference Manual.

# 6.10. Sample Application Program in VAX-11 FORTRAN

The FMS Sample Application program (SAMPFOR.FOR) is part of the FMS distribution kit. When FMS is installed, SAMPFOR.FOR is placed in the directory FMS\$EXAMPLES. Designed to be a demonstration program and learning tool, SAMPFOR.FOR shows most of the features provided by FMS. The entire Sample Application program appears at the end of this chapter.

#### 6.10.1. Form Driver Definition Files

The files FDVDEF.FOR, SMPACCOM.FOR, SMPREGCOM.FOR, SMPSTATUS.FOR, and SMPWORK.FOR are part of the Sample Application program package. When FMS is installed, these files are placed in the directory FMS\$EXAMPLES. They appear after the Sample Application source code.

FDVDEF.FOR contains a variety of codes for the Form Driver routines used in the Sample Application program. Although these codes have been created for use in SAMP.BAS, they can provide you with a helpful starting point as you create definitions for your own application program. The file FDVDEF.FOR includes:

FMS terminator codes

- Function key terminators returned from the FDV\$GET and FDV\$WAIT calls
- Form Driver key functions for use with the FDV\$DFKBD call
- User action routine (UAR) return codes, which are returned by the UARs to the Form Driver:
  - Field completion UAR return codes
  - Help UAR return codes
  - Function key UAR return codes
- VMS status codes returned when Form Driver routines are called as functions. These codes can be signaled.
- FMS status codes returned when the FDV\$STAT routine is called as a function
- Declarations of Form Driver routines

# 6.10.2. Command File for Building the Sample Application Program

The command file for building the Sample Application program includes all the information that you need to compile and link SAMPFOR.FOR. When FMS is installed, the command file is placed in the directory FMS\$EXAMPLES.

```
SAMPFOR, COM
$!
$ !
$ !
     Compile and link the FORTRAN version of the FMS V2 Sample Application

```

Note that in FORTRAN the record is read into the array and reference Read the remaining records into the check register, counting them. Set up the workspace for checks and fill in the check form OPEN(UNIT=5, STATUS='OLD', READONLY, FILE='FMS\$EXAMPLES:SAMP.DAT') the to the check number is via a substring rather than symbolically. Reached here without hittins end of file, should probably print demo. The last record has the current balance, and some record has with the account's name, address, and account number. 1,11 01/ last check number used (not necessarily the last record) As it is, just fall through and ignore remaining records READ (UNIT=5, FMT=20, END=100) REGARRAY(LASTREGNUM+1) Read From File SAMP.DAT into internal variables. READ(REGARRAY(LASTREGNUM)(1:4),'(14)') LASTCHNUM THEN message or something, except that this is just a IF ( REGARRAY(LASTREGNUM)(1:4) .NE. ' Other lansuases may access differently. READ (UNIT=5, FMT=10, END=100) ACCOUNT 'SMPFORTXT(REGISTER\_COMMON)'
'SMPFORTXT(ACCOUNT\_COMMON)' REGSIZE) LASTREGNUM = LASTREGNUM + 1 Open file, set account data DO WHILE (LASTREGNUM .LT. SUBROUTINE INIT\_ACCOUNT LASTREGNUM = 0 IMPLICIT NONE LASTCHNUM = 0 FORMAT(A) ENDIF FORMAT(A) INCLUDE CLOSE ( 5 ) ENDDO 100 ្ម 20 00000 000 000000  $\cup \cup \cup$ 

```
Set uP the check workspace once so we don't have to do it every time.
Reach here as result of end of file--last record tried didn't read.

                                                                                                                                                                                                                                                                                                                                           INTEGER
                                                                                                                                                                                                                                                                                                                                                               INTEGER
                                                                                                                                                                                                                   INTEGER
                                                                                                                                                                                                                                                                                INTEGER
                                                                                                                                                                                                                                                                                                    INTEGER
                                                                                                                                                                                                                                                                                                                                                                                   INTEGER
                                                                                                                                                                                                                                                                                                                                                                                                        INTEGER
                                                                                                                                                                                                                                                                                                                                                                                                                             INTEGER
                                                                                                                                                                 .....

# Chapter 7. Programming FMS Applications in VAX-11 PASCAL

The FMS Form Driver processes all Form Driver calls according to VAX-11 standards and languagespecific rules. These rules define how parameters are passed to the Form Driver and how values are returned to your program. Language-specific information is briefly presented in this manual. For more detail, refer to the VAX-11 PASCAL document set.

Your VAX-11 PASCAL application program must comply with the requirements of the VAX-11 PASCAL FMS interface. Topics discussed in this chapter include:

- Form Driver Routines
  - Invoking Form Driver Routines as Procedures
  - Accessing Form Driver Status Codes as Functions
- Parameter Passing in FMS
- Null Arguments
- Entry Point Definitions
- FMS Data Types
  - Character Strings
  - Longword Binary Integers
  - Word Binary Integers
- Non-FMS Data Types
- One-Dimensional Arrays
- Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area
- Precautions for Using FMS
- Data Conversion
- Sample Application Program in VAX-11 PASCAL

A sample program written in PASCAL (SAMPPAS.PAS) appears at the end of this chapter. Following the code for the Sample Application are Form Driver environment files which you may wish to include in your own application program. Command file information needed to build the Sample Application program is in Section 7.11.2.

Examples from the Sample Application are used throughout the text to illustrate language issues. Where appropriate examples from SAMPPAS.PAS do not exist, other examples are provided.

# 7.1. Form Driver Routines

You can call any FMS routine as a procedure or as a function. Syntax follows standard VAX-11 PASCAL requirements.

#### 7.1.1. Invoking Form Driver Routines as Procedures

You can invoke a Form Driver routine as a procedure as shown in the following examples:

```
FDV$WAIT ();
```

Calls the Form Driver routine FDV\$WAIT and passes no parameters.

FDV\$GET (FLDVAL := Option, FLDTRM := Terminator, FLDNAM := 'OPTION'

Calls the Form Driver routine FDV\$GET and passes three parameters.

See Appendix A for a complete list of Form Driver calls. The calling sequence for each Form Driver routine, data access codes, data types, and passing mechanisms are presented in language-independent notation specified by the VAX-11 Procedure Calling and Condition Handling Standard. For further detail about the VAX-11 Procedure Calling and Condition Handling Standard, refer to the *VAX-11 Run-Time Library Reference Manual*.

#### 7.1.2. Accessing Form Driver Status Codes as Functions

An FMS status code is returned to the calling program at the completion of all Form Driver calls. To receive the returned status code from a Form Driver routine, you activate the routine with a function designator. Note that this returns a standard VMS status code. For portability, other status mechanisms can also be used. For more information, see the *VAX-11 FMS Form Driver Reference Manual*, Chapter 2.

The following statement calls FDV\$GET as an FMS function:

STATUS\_RETURN = FDV\$GET (OPTION, TERMINATOR, 'OPTION');

#### 7.2. Parameter Passing in FMS

The parameter passing mechanism refers to the way in which data is passed to a called routine. The VAX-11 Procedure Calling Standard has three methods for passing parameters:

- By reference
- By descriptor
- By value

FMS routines, however, expect parameters to be passed only by reference and by descriptor.

**By reference** specifies that the storage location of the parameter is passed to the routine. FMS expects integers to be passed by reference which is the PASCAL default passing mechanism for all data types.

**By descriptor** specifies that the address of a descriptor data structure is passed to the called routine. FMS expects character strings and arrays to be passed by descriptor. The default passing mechanism for conformant arrays (those that assume the characteristics of their actual arguments) is by descriptor. However, the PASCAL default passing mechanism for character strings is by reference. Consequently, the [CLASS\_SJ attribute is used to force use of the [CLASS\_SJ string descriptor mechanism for passing character strings to the FMS routine. For example:

```
[ASYNCHRONOUS] FUNCTION FDV$RETCX (
    VAR tca : [VOLATILE] ARRAY [$11..$u1:INTEGER] OF INTEGER;
    VAR wksp : [VOLATILE] ARRAY [$12..$u2:INTEGER] OF INTEGER;
    VAR frmnam : [CLASS_S] PACKED ARRAY [$13..$u3:INTEGER] OF CHAR;
    VAR uarval : [CLASS_S] PACKED ARRAY [$14..$u4:INTEGER] OF CHAR;
    VAR curpos : [VOLATILE] INTEGER;
    VAR fldtrm : [VOLATILE] INTEGER;
    VAR insovr : [VOLATILE] INTEGER;
    VAR hlpnum : [VOLATILE] INTEGER;
```

### 7.3. Null Arguments

When the call syntax includes optional parameters and you do not wish to specify all of the information, you can use null arguments. Each optional parameter can be omitted to simplify your program. Optional parameters to the right of the last required parameter can simply be omitted from the call. In the following example, the FDV\$GETAL call passes only the field terminator value:

```
FDV$GETAL (FLDTRM := Terminator);
```

PASCAL has two ways to specify null arguments. One approach is to use non-positional syntax. You use named parameters and do not reference the omitted parameters. The other approach is to use positional parameters and represent null parameters by a comma. Thus, the following two statements are equivalent:

```
FDV$GETAL (FLDTRM := Terminator)
FDV$GETAL (Terminator,,,)
```

All optional parameters must be declared with a default value (usually %IMMED 0).

VAX-11 PASCAL supports null arguments by allowing you to supply a default immediate value of zero in the declaration of the routine to which the null argument is to be passed. For example, in the declaration of the function FDV\$ATERM, a default immediate value of zero is supplied to the parameters size, channel, and terminal.

```
[ASYNCHRONOUS] FUNCTION FDV$ATERM (
    VAR tca : [VOLATILE] ARRAY [$11..$ui : INTEGER] OF INTEGER;
    size : INTEGER := %IMMED 0;
    channel : INTEGER := %IMMED 0;
    terminal : INTEGER := %IMMED 0) : INTEGER; EXTERNAL
```

A call to the FDV\$ATERM routine declared above follows:

FDV\$ATERM (terminal, 12, 1,);

The following call is equivalent but it leaves off the trailing comma:

FDV\$ATERM (terminal, 12, 1);

#### 7.4. Entry Point Definitions

The most difficult part of calling external routines from PASCAL is defining the entry points. Every entry point used in a PASCAL program must be declared with all its parameters and their types.

It is extremely important to have complete, correct definitions of all the entry points and their arguments. Your program will not compile if the number, data types, and uses of arguments in a call do not agree with their declarations. The include file FDVDEF.PAS contains definitions for the Form Driver constants and entry points. To access the Form Driver entry points, your program must inherit the precompiled environment file FDVDEF.PEN. The following steps can be performed:

- 1. Obtain the source file FDVDEF.PAS from the directory called FMS\$EXAMPLES.
- 2. Compile the file FDVDEF.PAS to produce the precompiled environment file FDVDEF.PEN:
  - \$ PASCAL/ENVIRONMENT FDVDEF.PAS
- 3. Incorporate the precompiled environment file FDVDEF.PEN into your program:

[INHERIT('FDVDEF, PEN')]PROGRAM name...;

Many calls to FMS have a variable number of arguments. If you use the file FDVDEF.PEN, you do not have to worry about these variations in specified arguments because FDVDEF.PEN has the entry points for the Form Driver defined.

### 7.5. FMS Data Types

#### 7.5.1. Character Strings

The character string is one of the general data types used by FMS. For example, the FDV\$GET call passes the character strings for field value (Option) and field name ('OPTION'):

FDV\$GET (OPTION, TERMINATOR, 'OPTION');

#### 7.5.1.1. Declaring Fixed-Length Strings

Although FMS accepts both varying-length and fixed-length strings as parameters, it treats all strings as if they were fixed length. In other words, FMS does not alter the length of a varying-length string descriptor when it returns values to the output parameters. When you use fixed-length strings, you must be certain that your strings are initially declared to be long enough to accommodate your FMS data. When you use varying-length strings, be certain that the upper boundary of the string is large enough to accommodate the maximum string length expected for that variable.

Two approaches are available for satisfying the fixed-length string constraints of FMS. One option is to declare your fixed-length strings to be the exact length of the FMS data to be returned. You can use the FMS/DESCRIPTIONIIIECLARATIONS command to get the length of the strings.

Alternatively, a single string variable can be used in different FMS calls to transfer data to or from several forms and fields. You must declare the string variable to be at least as large as the longest field value string that will be returned to your program. You can use the FMS/DESCRIPTION/BRIEF command to get this information. Use the FDV\$RETLE call to return the length of the valid portion of the field value in the string variable. This length can then be used when referencing the data that was entered in the field.

```
FDV$GET (ACCOUNT, TERMINATOR, 'FIELD');
FDV$RETLE ( LENGTHFIELD, 'FIELD');
```

```
WRITE (SUBSTR (ACCOUNT, 1, LENGTHFIELD));
```

After the FDV\$RETLE call, LENGTHFIELD is equal to the length of the field named 'FIELD.' It is also equal to the the valid portion of the string that is defined by the string descriptor ACCOUNT. LENGTHFIELD can now be used to reference the data that was entered in the field named 'FIELD'. If you do not use the PASCAL SUBSTR function when designating ACCOUNT, you will designate the entire variable, including any blanks used by the Form Driver to pad the string.

A useful application of the FDV\$RETLE call is in general purpose user action routines.

#### 7.5.2. Longword Binary Integers

The longword binary integer is another general data type used by FMS. For example, the FDV \$ATERM call passes the longword value for terminal control area size (12) and logical I/O channel number (2):

FDV\$ATERM (TCA := Tca, Size := 12, Channel := 2);

Numeric arguments must be longword binary integers. If you try to pass other numeric types to the Form Driver, the calls do not work properly. An exception is the FDV\$DFKBD call (see the next section).

#### 7.5.3. Word Binary Integers

The defkbd argument is a word integer array passed when the FDV\$DFKBD routine is called. FMS expects arrays to be passed by descriptor.

# 7.6. Non-FMS Data Types

PASCAL data types that are not recognized by FMS can be used in your PASCAL application program provided they are not passed to the Form Driver.

# 7.7. One-Dimensional Arrays

One-dimensional arrays are structures that can be used in FMS for the following arguments:

- tca (terminal control area)
- wksp (workspace)
- mloc (memory location)
- defkbd (define keyboard)

You must provide FMS with storage space for these arguments. You can do that by declaring them to be:

- · longword integer arrays or character strings for tca, wksp, and mloc
- word integer arrays for defkbd

In the Sample Application program, the tca, wksp, and mloc arguments are passed to several Form Driver routines. These arguments are declared to be integer array variables. You may alternatively declare these variables to be character strings. (The strings can be static or varying length but must be extended to the proper length.) If you declare these variables to be character strings, you need to redefine all of the entry points that reference terminal control area, workspace, and memory location. Otherwise, you will get compile errors.

The following declarations establish names and storage for the integer array variables Workspace, Checkwksp, Tca, and Menu\_form:

```
VAR Workspace : [VOLATILE] ARRAY [1..]3] OF INTEGER; { General workspace }
Checkwksp : [VOLATILE] ARRAY [1..]3] OF INTEGER; { Check workspace }
Tca : [VOLATILE] ARRAY [1..3] OF INTEGER; { Term Control Area }
```

forms }

# 7.8. Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area

The FMS workspace, terminal control area, and run-time memory-resident form area variables are character strings or longword integer arrays. These variables should be declared with the VOLATILE attribute.

The Form Driver needs 12 bytes to associate user information about each workspace and terminal control area. The allocation for a run-time memory-resident form area must be the size of the form. The space for all of these variables is allocated by your application program. Note that FMS uses *only* 12 bytes of space for the workspace and terminal control area allocation. Any allocation greater than 12 bytes is wasted. You declare your workspace, terminal control area, and run-time memory-resident form area only once. FMS remembers their addresses after the addresses have been initially passed to the Form Driver.

For each workspace, the Form Driver also allocates an additional amount of storage space based on your estimate of the amount of memory needed to store your largest form. If your estimate is too small, the Form Driver will allocate more space automatically, but performance may be affected. An adequate estimate results in more efficient operation of the Form Driver. You can use the FMS/ DIRECTORY/FULL command to find out how much space to allocate.

In the following example from the Sample Application program, workspace is allocated and the FDV\$AWKSP routine is called. When the FDV\$AWKSP routine is called, the first argument (WORKSPACE) specifies the area of memory to be used for your workspace. In the declaration section of your program, 12 bytes (3 longwords) are allocated to workspace storage. The second argument in the FDV\$AWKSP call specifies an estimate of the workspace size (2000 bytes) that you will need to display the largest form in your application.

VAR Workspace : [VOLATILE] ARRAY [1..3] OF INTEGER; FDV\$AWSKP (WORKSPACE,2000);

# 7.9. Precautions for Using FMS

#### 7.9.1. Memory Areas Used Exclusively by FMS

The locations for terminal control area, workspace, and run-time memoryresident form area are used exclusively by FMS. The terminal control area and workspace are attached with the FDV\$ATERM and FDV\$AWKSP calls and remain allocated until the FDV\$DTERM and FDV\$DWKSP calls are issued or until the program ends. The run-time memory-resident form area, used in the FDV\$READ call, remains allocated until the FDV\$DEL call is issued or until the program ends. You never touch the terminal control areas, workspaces, or run-time memory-resident form areas in your program once you have declared them except to pass their addresses to the Form Driver.

#### 7.9.2. Why You Should Use the VOLATILE Attribute

Parameters to the following Form Driver routines should be used with caution:

FDV\$ATERM	Attach terminal
FDV\$AWKSP	Attach form workspace
FDV\$READ	Read form into memory
FDV\$SSRV	Specify status reporting variables

For example, once an FDV\$SSRV call is issued, the program variables that contain the FMS status and RMS status become volatile and can change at any call point. As a general rule, you should place the status variables in static storage.

In cases where you need both the FMS and RMS statuses, the FDV\$STAT routine can be used. Note that only the FDV\$STAT and FDV\$SSRV calls provide RMS status. With the FDV\$STAT routine, you do not have to worry about volatility.

The locations for terminal control area, workspace, run-time memory-resident form area, and status reporting variables must all continue to exist while the Form Driver is using them. They must remain until the terminal control area and workspace are detached, until forms in memory location are deleted, and until the status reporting variables are not used anymore. The variables can be protected by declaring them in static storage with the VOLATILE attribute; otherwise, the compiler might place them in dynamic storage or reuse their storage area.

# 7.10. Data Conversion

FMS uses only ASCII character strings to display data. All information displayed on the terminal screen, and all information received from the terminal operator, will be represented as ASCII field values. Any manipulation of numeric data requires conversion of ASCII character strings to

numeric data, and conversion of numeric data back to ASCII character strings. In the following discussion of conversion routines, you should assume that the receiving data type can support the largest number that is likely to be generated.

In the Sample Application, the following steps are taken to get a new account balance after writing a check:

```
WITH Registeritem[LastRegisterNumber] D0
BEGIN
FDV$RET (FLDVAL := Amtpay, FLDNAM := 'AMTPAY');
READV (Amtpay, Amount_paid);
Current_Balance := Current_Balance - Amount_paid;
TotalPayment := TotalPayment + Amount_paid;
FDV$PUT (FLDVAL := Integer_to_Text (Current_Balance),
FLDNAM := 'BALANCE');
```

In this example, the READV procedure is used to convert the character string expression Amtpay to an integer variable Amount\_paid, which is used to hold the data item's value. The integer value of the variable Amount\_paid is subtracted from the integer value of the variable Current\_Balance to produce a new value for Current\_Balance. The value of Amount\_paid is also added to the integer value of the variable TotalPayment to produce a new value for TotalPayment.

After the data operations have been completed, the function Integer\_to\_Text converts the integer value of the variable Current\_Balance to the corresponding ASCII character expression. (Note that the function Integer\_to\_Text is not a PASCAL predeclared function; it is a user-defined function created for the Sample Application program.) After the value for balance has been converted to a character expression, it is displayed in a right-justified field 'BALANCE.' The rightmost digit from the program is displayed in the field's rightmost character position. The remaining digits of the character

expression are placed to the left of the rightmost digit. If output is longer than the field, FMS truncates on the left. (The Form Driver displays a data length error message (FDV\$..DLN) only if you have set FMS Debug mode.)

# 7.11. Sample Application Program in VAX-11 PASCAL

The FMS Sample Application program (SAMPPAS.PAS) is part of the FMS distribution kit. When FMS is installed, SAMPPAS.PAS is placed in the directory FMS\$EXAMPLES. Designed to be a demonstration program and learning tool, the Sample Application shows most of the features provided by FMS. The entire Sample Application program appears at the end of this chapter.

#### 7.11.1. Form Driver Definition Files

The file FDVDEF.PAS is part of the Sample Application program package. When FMS is installed, FDVDEF.PAS is placed in the directory FMS\$EX AMPLES. The FDVDEF.PAS file appears after the Sample Application source code.

FDVDEF.PAS contains a variety of codes for the Form Driver routines used in the Sample Application program. Although these codes have been created for use in SAMP.PAS, they can provide you with a helpful starting point as you create definitions for your own application program. The file FDVDEF.PAS includes:

- Predeclared data types
- FMS terminator codes
- Function key terminators returned from the FDV\$GET and FDV\$WAIT calls
- Form Driver key functions for use with the FDV\$DFKBD call
- User action routine (UAR) return codes, which are returned by the UARs to the Form Driver:
  - Field completion UAR return codes
  - Help UAR return codes
  - Function key UAR return codes
- VMS status codes returned when Form Driver routines are called as functions. These codes can be signaled.
- FMS status codes returned when the FDV\$STAT routine is called as a function
- Form Driver entry point definitions

# 7.11.2. Command File for Building the Sample Application Program

The command file for building the Sample Application program includes all the information that you need to compile and link SAMPPAS.PAS. When FMS is installed, the command file is placed in the directory FMS\$EXAMPLES.

\$! SAMPPAS, COM \$! **\$**! Compile and link the PASCAL version of the FMS V2 Sample Application \$! SAMPPAS.PAS **\$** ! The PASCAL source files are: **\$**! FDVDEF, PAS \$! **\$**! FUNCTION VALIDI;

case sensitivity by using the force upper case field attribute string. This routine can be used with any form and field since For example an assoc. value string 'aar' implies that only the letters a, 9, and r are allowed. UAR associated data has in it the legal characters allowed, A string ' aar' means that blank is acceptable in addition (that is, it checks for correct case). You can get around excert that blank is not allowed unless it appears before ( UAR for field validation of any one character field. The to a, 4, and r. Note that this routine is case sensitive and putting only capitals into the UAR associated value it determines the context for itself. the first trailing blank.

## Chapter 8. Programming FMS Applications in VAX-11 PL/I

The FMS Form Driver processes all Form Driver calls according to VAX-11 standards and languagespecific rules. These rules define how arguments are passed to the Form Driver and how values are returned to your program. Language-specific information is briefly presented in this manual. For more detail, refer to the VAX-11 PL/I document set.

Your VAX-11 PL/I application program must comply with the requirements of the VAX-11 PL/I FMS interface. Topics discussed in this chapter include:

- Form Driver Routines
  - Invoking Form Driver Routines as Procedures
  - Accessing Form Driver Status Codes as Functions
- Argument Passing in FMS
- Null Arguments
- Defining the Entry Points
- FMS Data Types
  - Character Strings
  - Longword Binary Integers
  - Word Binary Integers
- Declarations
- Non-FMS Data Types
- One-Dimensional Arrays
- Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area
- Precautions for Using FMS
- Data Conversion
- Sample Application Program in VAX-11 PL/I

A sample program written in PL/I (SAMPPLI.PLI) appears at the end of this chapter. Following the code for SAMPPLI.PLI are Form Driver definition files created for the sample program. Command file information needed to build the Sample Application program is in Section 8.12.2.

Examples from the Sample Application are used throughout the text to illustrate language issues. Where appropriate examples from SAMP-PLI.PLI do not exist, other examples are provided.

## 8.1. Form Driver Routines

You can call any FMS routine as a subroutine or as a function. Syntax follows standard VAX-11 PL/I requirements.

#### 8.1.1. Invoking Form Driver Routines as Procedures

You use the procedure call statement to invoke an FMS Form Driver routine. For example:

```
CALL FDV$WAIT;
```

Calls the Form Driver routine FDV\$WAIT and passes no arguments.

CALL FDV\$GET (OPTION, TERMINATOR, 'OPTION');

Calls the Form Driver routine FDV\$GET and passes three arguments.

See Appendix A for a complete list of Form Driver calls. The calling sequence for each Form Driver routine, data access codes, data types, and passing mechanisms are presented in language-independent notation as specified by the VAX-11 Procedure Calling and Condition Handling Standard. For further detail about the VAX-11 Procedure Calling and Condition Handling Standard, refer to the VAX-11 Run-Time Library Reference Manual.

#### 8.1.2. Accessing Form Driver Status Codes as Functions

An FMS status code is returned to the calling program at the completion of all Form Driver calls. To receive the returned status code from a Form Driver routine, you activate the routine with a function reference rather than with a call statement.

If you want to call an FMS routine as a function, you must specify the RETURNS option with a FIXED BIN (31) data type. The following statements reference FDV\$GET as an FMS function:

## 8.2. Argument Passing in FMS

The argument passing mechanism refers to the way in which data is passed to a called routine. The VAX-11 Procedure Calling Standard has three methods for passing arguments:

- By reference
- By descriptor
- By value

FMS routines, however, expect arguments to be passed only by reference and by descriptor.

**By reference** specifies that the storage location of the argument is passed to the routine. FMS expects integers to be passed by reference, which is the PL/I default passing mechanism for integers.

**By descriptor** specifies that the address of a descriptor data structure is passed to the called routine. FMS expects character strings and arrays to be passed by descriptor. PL/I automatically passes character strings and arrays by descriptor if the parameter descriptors show a variable extent, as they do in the FMS include files FDVDEFCAL.PLI and FDVDEFFNC.PLI. Generally (in the EXTERNAL ENTRY declaration for FMS procedures), specify all character strings and integer arrays in the parameter list with (\*). This will force PL/I to always pass arguments by descriptor, which is what FMS expects.

## 8.3. Null Arguments

When the call syntax includes optional arguments and you do not wish to specify all of the information, you can use null arguments. Any optional arguments can be omitted to simplify your program. A comma functions as a placeholder for each null argument. Optional arguments to the right of the last required argument can simply be omitted from the call. In the following example, the FDV \$GETAL call passes only the field terminator value:

```
CALL FOV$GETAL ( ,FLDTRM);
```

## 8.4. Entry Point Definitions

The most difficult part of calling external routines from PL/I is defining the entry points. Every entry point used in a PL/I program must be declared with all its parameters and their types.

It is extremely important to have complete, correct definitions of all the entry points and their arguments. Your program may get warning mes sages if the number, data types, and uses of arguments in a call do not agree with their declarations. The include files FDVDEFCAL.PLI and FDVDEFFNC.PLI contain definitions for the entry points for the Form Driver. FDVDEFCAL.PLI is the file for procedure calls. FDVDEFFNC.PLI is the file for function calls.

Many calls to FMS have a variable number of arguments. If you use the include file FDVDEFCAL.PLI or FDVDEFFNC.PLI, you do not have to worry about these variations in specified arguments because these include files have the entry points for the Form Driver defined.

## 8.5. FMS Data Types

#### 8.5.1. Character Strings

The character string is one of the general data types used by FMS. For example, the FDV\$GET call passes the character strings for field value (OPTION) and field name ('OPTION'):

CALL FDV\$GET (OPTION, TERMINATOR, 'OPTION');

#### 8.5.1.1. Defining Character Strings

Use only CHARACTER for strings passed to FMS. Do not use the CHARACTER VARYING attribute. You must be certain that your strings are declared to be long enough to accommodate your FMS data.

Two approaches are available for satisfying the fixed-length string requirements of FMS. One option is to declare your fixed-length strings to be the exact length of the FMS data to be returned. You can use the FMS/DESCRIPTION/DECLARATIONS command to get the length of the strings.

Alternatively, you can use a single string variable in different FMS calls to transfer data to or from several forms and fields. You must declare the string variable to be at least as large as the longest field

value string that will be returned to your program. You can use the FDV\$RETLE call to return the length of the valid portion of the field value in the string variable. This length can then be used when referencing the data that has been entered in the field.

```
DECLARE ACCOUNT CHARACTER(100);
.
.
.
CALL FDV$GET (ACCOUNT, TERMINATOR, 'FIELD');
CALL FDV$RETLE (LENGTHFIELD, 'FIELD');
.
.
.
PUT LIST (SUBSTR (ACCOUNT, 1, LENGTHFIELD));
```

After the execution of the FDV\$RETLE call, LENGTHFIELD is equal to the length of the field named 'FIELD'. It is also equal to the valid portion of the variable ACCOUNT. LENGTHFIELD can now be used when referencing the data that was entered in the field named 'FIELD', and that is now in the variable ACCOUNT. If you do not use the PL/I SUBSTR function when referencing ACCOUNT, you will reference the entire variable, including any blanks used by the Form Driver to pad the string.

A useful application of the FDV\$RETLE call is in general purpose user action routines.

#### 8.5.2. Longword Binary Integers

The longword binary integer is another general data type used by FMS. For example, the FDV \$ATERM call passes the longword value for terminal control area size (12) and logical I/O channel number (2):

CALL FDV\$ATERM (TCA, 12, 2);

Numeric arguments must be fixed binary (31) integers. If you try to pass other numeric types to the Form Driver, the calls will not work properly. An exception is the FDV\$DFKBD call (see the following section).

#### 8.5.3. Word Binary Integers

The defkbd argument is a word integer array passed when the FDV\$DFKBD routine is called. FMS expects arrays to be passed by descriptor.

## 8.6. Declarations

If you do whole form processing with the FDV\$GETAL, FDV\$PUTAL, and FDV\$RETAL routines, you can use the FMS/DESCRIPTION/DECLARATIONS command to produce a file of declarations describing the transferred data. Although these declarations are not directly usable in your PL/I program, they closely resemble PL/I syntax. You can edit them and include them in your application program.

## 8.7. Non-FMS Data Types

PL/I data types that are not recognized by FMS can be used in your PL/I application program provided they are not passed to the Form Driver. Using the Form Driver entry points correctly

declared in your program, PL/I converts input arguments of non-FMS data type to arguments of the correct type by creating dummy arguments. However, you will not be given access to the values returned by the Form Driver to the output arguments. To allow non-FMS data types in your program to interact with FMS, use the PL/I conversion routines explicitly (see the VAX-11 PL/I document set).

## 8.8. One-Dimensional Arrays

One-dimensional arrays are structures that can be used in FMS for the following arguments:

- tca (terminal control area)
- wksp (workspace)
- mloc (memory location)
- defkbd (define keyboard)

You must provide FMS with storage space for these arguments. You can do that by defining them to be:

- · contiguous longword integer arrays or character strings for tca, wksp, and mloc
- contiguous word integer arrays for defkbd

In the Sample Application program, the tca, wksp, and mloc arguments are passed to several Form Driver routines. These arguments are defined as integer array variables. You may alternatively define these arguments to be character strings. If you declare these variables to be character strings, you need to redefine all of the entry points that reference terminal control area, workspace, and memory location. Otherwise, you will get compile errors.

The following declarations establish names and storage for the integer array variables WORKSPACE, CHECKWKSP, TCA, and MENU\_FORM:

```
DCLWORKSPACE (3) FIXED BIN (31);/* General workspace*/DCLCHECKWKSP (3) FIXED BIN (31);/* Check workspace*/DCLTCA(3) FIXED BIN (31);/* Terminal Control Area */DCLMENU_FORM (500) FIXED BIN (31);/* Storage for memory-resident form*/
```

## 8.9. Allocation: Workspace, Terminal Control Area, and Run-Time Memory-Resident Form Area

The FMS workspace, terminal control area, and run-time memory-resident form area variables are character strings or longword integer arrays. These variables should be declared EXTERNAL. Note that this is not done in the Sample Application program. The sample program's structure protects the workspaces, terminal control areas, and run-time memory-resident form areas implicitly.

The Form Driver needs 12 bytes to associate user information about each workspace and terminal control area. The allocation for a run-time memory-resident form area must be the size of the form. The space for all of these variables is allocated by your application program. Note that FMS uses *only* 12 bytes of space for the workspace and terminal control area allocation. Any allocation greater than 12 bytes is wasted. You declare your workspace, terminal control area, and run-time memory-resident

form area only once. FMS remembers their addresses after the addresses have been initially passed to the Form Driver.

For each workspace, the Form Driver also allocates an additional amount of storage based on your estimate of the amount of memory needed to store your largest form. If your estimate is too small, the Form Driver allocates more space automatically, but performance may be affected. An adequate estimate results in a more efficient operation of the Form Driver. You can use the FMS/DIRECTORY/ FULL command to find out how much space to allocate.

In the following example from the Sample Application program, workspace is allocated and the FDV \$AWKSP call is issued. When the FDV\$AWKSP routine is called, the first argument (WORKSPACE) specifies the area of memory to be used for your workspace. The second argument specifies an estimate of the workspace size (2000 bytes) that you will need to display the largest form in your application.

DCL WORKSPACE (3) FIXED BIN (31); \*/ General workspace \*/ CALL FDV\$AWKSP (WORKSPACE, 2000);

## 8.10. Precautions for Using FMS

#### 8.10.1. Memory Areas Used Exclusively by FMS

The locations for terminal control area, workspace, and run-time memoryresident form area are used exclusively by FMS. The terminal control area and workspace are attached with the FDV\$ATERM and FDV\$AWKSP calls and remain allocated until the FDV\$DTERM and FDV\$DWKSP calls are issued or until the program ends. The run-time memory-resident form area, used in the FDV\$READ call, remains allocated until the FDV\$DEL call is issued or until the program ends. You never touch the terminal control areas, workspaces, or run-time memory-resident form areas in your program except to pass their addresses to the Form Driver.

#### 8.10.2. Why You Should Use the EXTERNAL Attribute

Parameters to the following Form Driver routines should be used with caution:

FDV\$ATERM	Attach terminal
FDV\$AWKSP	Attach form workspace
FDV\$READ	Read form into memory
FDV\$SSRV	Specify status reporting variables

For example, once an FDV\$SSRV call is issued, the program variables that contain the FMS status and RMS status become volatile and can change at any call point. As a general rule, you should place the status reporting variables in static storage.

In cases where you need both the FMS and RMS statuses, the FDV\$STAT routine can be used. Note that only the FDV\$STAT and FDV\$SSRV calls provide RMS status. With the FDV\$STAT routine, you do not have to worry about volatility.

The locations for terminal control area, workspace, run-time memory-resident form area, and status reporting variables must all continue to exist while the Form Driver is using them. They must remain allocated until the terminal control area and workspace are detached, until forms in memory location are deleted, and until the status reporting variables are no longer used. The variables can be protected

by declaring them EXTERNAL; otherwise, the compiler might place them in dynamic storage or reuse their storage area.

## 8.11. Data Conversion

FMS uses only ASCII character strings to display data. AH information displayed on the terminal screen, and all information received from the terminal operator, is represented as ASCII field values. Any manipulation of numeric data requires conversion of ASCII character strings to numeric data, and conversion of numeric data back to ASCII character strings. In the following discussion of conversion routines, you should assume that the receiving data type can support the largest number that is likely to be generated.

In the Sample Application, the following steps are taken to get a new ac count balance after writing a check:

```
CALL FDV$RET (REGARRAY.AMTPAY (LASTREGNUM), 'AMTPAY');
AMTPAY = FIXED (REGARRAY.AMTPAY (LASTREGNUM), 31);
BALANCE = BALANCE - AMTPAY;
TOTPAY = TOTPAY + AMTPAY;
CALL FDV$PUT (CENTS (BALANCE), 'BALANCE');
CENTS: PROCEDURE (PENNIES) RETURNS (CHAR(*));
DCL PENNIES FIXED BIN (31);
DCL CHAR_PENNIES PICTURE 'ZZZ999';
CHAR_PENNIES = PENNIES;
RETURN (CHAR_PENNIES);
```

END CENTS;

In this example, the PL/I FIXED function is used to convert the string expression REGARRAY.AMTPAY(LASTREGNUM) to a fixed-point integer variable with a specified number of binary digits (31) used to hold the data item's value. The integer value of AMTPAY is subtracted from the integer value of BALANCE to produce a new value for BALANCE. The value of AMTPAY is also added to the integer value of TOTPAY to produce a new value for TOTPAY.

After the data operations have been completed, an integer-to-ASCII character string conversion is accomplished. Using an assignment to a picture variable, the user-created CENTS function is used to convert the integer variable BALANCE to an ASCII character expression BALANCE. The value for the balance is displayed in a right-justified field 'BALANCE'. The rightmost digit from the program is displayed in the field's rightmost character position. The remaining digits of the character expression are placed to the left of the rightmost digit. If input is longer than the field, FMS truncates on the left. (The Form Driver displays a data length error message (FDV\$\_DLN) only if you have set FMS Debug mode.)

Note that in this example the output goes to a field with a decimal point field-marker character. In the presence of a decimal point field marker, the Form Driver creates strange-looking output for singledigit data items. The output will be a period followed by a space and then digit rather than .01, for example. In the above example, the assignment to a picture variable is used to prevent this kind of unconventional output.

The PL/I built-in function CHARACTER converts a number to a character string with one or two leading blanks (see the VAX-11 PL/I documentation for details). If you display this string in a left-justified field, you must take these leading blanks into consideration. Your program can use the

CHAR ACTER function for data conversion operations if field markers will not create a confusing appearance.

For other conversion options, see the general conversion routines in the VAX-11 Run-Time Library Reference Manual.

# 8.12. Sample Application Program in VAX-11 PL/I

The FMS Sample Application program (SAMPPLI.PLI) is part of the FMS distribution kit. When FMS is installed, SAMPPLI.PLI is placed in the directory FMS\$EXAMPLES. Designed to be a demonstration program and learning tool, SAMPPLI.PLI shows most of the features provided by FMS. The entire Sample Application program appears at the end of this chapter.

#### 8.12.1. Form Driver Definition Files

The files FDVDEFCAL.PLI and FDVDEFFNC.PLI are part of the Sample Application program package. When FMS is installed, FDVDEFCAL.PLI and FDVDEFFNC.PLI are placed in the directory FMS\$EXAMPLES. The FDVDEFCAL.PLI and FDVDEFFNC.PLI files appear after the Sample Application source code.

FDVDEFCAL.PLI and FDVDEFFNC.PLI contain a variety of codes for the Form Driver routines used in the Sample Application program. Although these codes have been created for use in SAMPPLI.PLI, they can provide you with a helpful starting point as you create definitions for your own application program.

FDVDEFCAL.PLI is the include file for SAMPPLI.PLI with all Form Driver references as calls. FDVDEFFNC.PLI is the include file for SAMPPLI.PLI with all Form Driver references as functions. The files FDVDEFCAL.PLI and FDVDEFFNC.PLI include:

- FMS terminator codes
- Function key terminators returned from the FDV\$GET and FDV\$WAIT calls
- Form Driver key functions for use with the FDV\$DFKBD call
- User action routine (UAR) return codes, which are returned by the UARs to the Form Driver:
  - Field completion UAR return codes
  - Help UAR return codes
  - Function key UAR return codes
- VMS status codes returned when Form Driver routines are called as functions. These codes can be signaled.
- FMS status codes returned when the FDV\$STAT routine is called as a function
- Declarations of Form Driver routines
## 8.12.2. Command File for Building the Sample Application Program

The command file for building the Sample Application program includes all the information that you need to compile and link SAMPPLI.PLI. When FMS is installed, the command file is placed in the directory FMS\$EXAMPLES.

```
$!
      SAMPPLI, COM
$ !
      Compile and link the PL/I version of the FMS V2 Sample Application
$!
$!
                                         SAMPPLI, PLI
$!
      The PLI source files are:

```
Delete a form from dynamic memory resident form list just to show how.
Detach workspaces (not really necessary since DTERM would do it).

```

If neither

If the

/\* bound is given, nothing is checked, everything succeeds.

If one of the bounds isn't siven, it isn't checked for.

```

# Appendix A. VAX-11 FMS Form Driver Calls

## A.1. VAX-11 Language-Independent Notation

Form Driver routines are invoked according to rules specified in the VAX-11 Procedure Calling and Condition Handling Standard (Appendix C of the *VAX-11 Run-Time Library Reference Manual*). The complete notation for describing VAX-11 calls is documented in Appendix C of the *VAX-11 Guide to Creating Modular Library Procedures*.

Form Driver routines can be invoked as subroutines or as functions:

#### As a subroutine CALL FDV\$xxx (parameter1, parameter2,...)

#### As a function VMS\_stat.wlc.v = FDV\$xxx (parameter1, parameter2,...)

The access type, data type, passing mechanism, and parameter form are described in the following prescribed order:

<parameter-name>.<access type><data type>.<passing mechanism><parameter
form>

#### Example

For the FDV\$GET call the fldval, fldtrm, fldnam, and fldidx parameters are described as follows:

### FDV\$GET (fldval.wt.dxl,fldtrm.wl.r,fldnam.rt.dx1[,fldidx.rl.r]

The notation for each parameter is explained below. Note that every Form Driver call returns a VMS status code in the form **VMS\_stat.wlc.v.** 

Parameter	<access type=""></access>	<data type=""></data>	<passing mechanism&gt;</passing 	<pre>&gt;parameter form&gt;</pre>
fldval	w Write-only access	<i>i</i> Character-coded text string	d By descriptor	x1 Fixed-length or dynamic string descriptor
fldtrm	w Write-only access	l Longword integer (signed)	r By reference	_
fldnam	r Read-only access	<i>i</i> Character-coded text string	d By descriptor	x1 Fixed-length or dynamic string descriptor
fldidx	r Read-only access	l Longword integer (signed)	r By reference	_

## A.2. Procedure Parameter Notation for Form Driver Calls

FMS uses a subset of the OpenVMS procedure parameter notation. The following table explains the notation used for access type, data type, passing mechanism, and parameter form.

Notation	<access type=""></access>	Comments
m	Modify access	Parameters for both input and output
r	Read-only access	Parameters for input
W	Write-only access	Parameters for output

Notation	<data type=""></data>
a	Virtual address
1	Longword integer (signed)
lc	Longword return status
t	Character-coded text string
v	Aligned bit string
w	Word integer (signed)

Notation	<passing mechanism=""></passing>	Comments
d	By descriptor	FMS passing mechanism for character strings and integer arrays
r	By reference	FMS passing mechanism for integers

Notation	<pre><parameter form=""></parameter></pre>
a	Array reference or descriptor
x1	Fixed-length or dynamic string descriptor

## A.2 Procedure Parameter Notation for Form Driver Calls

FMS uses a subset of the VAX-11 procedure parameter notation. The following table explains the notation used for access type, data type, passing mechanism, and parameter form.

Notation	<access type=""></access>	Comments
m	Modify access	Parameters for both input and output
r	Read-only access	Parameters for input
w	Write-only access	Parameters for output
Notation	<data type=""></data>	
a	Virtual address	
1	Longword integer (signed)	
lc	Longword return status	
t	Character-coded text strin	g
v	Aligned bit string	
w	Word integer (signed)	
Notation	<passing mechanism=""></passing>	Comments
d	By descriptor	FMS passing mechanism for character strings and integer arrays
r	By reference	FMS passing mechanism for integers
Notation	<parameter form=""></parameter>	
a	Array reference or descrip	tor
<b>x</b> 1	Fixed-length or dynamic string descriptor	

Call	Procedure Parameter Notation
ADLVA	FDV\$ADLVA (video.ml.r)
	video attributes code of data line
	Alters the data line video attributes. You can specify Blink, Bold, Reverse, and/or Underline.
AFCX	FDV\$AFCX (insovr.rl.r,curpos.rl.r[,fldnam.rt.dx1[,fldidx.rl.r]])
	insovrInsert/Overstrike mode of fieldcurposcursor position within fieldfldnamfield namefldidxfield index
	Alters the default field context of the specified field. You can specify Insert or Overstrike mode and cursor position in the field before any GET operation involving that field.
AFVA	FDV\$AFVA (video.ml.r[,fldnam.rt.dx1[,fldidx.rl.r]])
	video video attributes code for field fldnam field name fldidx field index
	Alters the field video attributes.
ATERM	FDV\$ATERM (tca.ml.da,size.rl.r,channel.rl.r[,trmnal.rt.dx1])
	or FDV\$ATERM (tca.mt.dx1,size.rl.r,channel.rl.r[,trmnal.rt.dx1])
	tcaterminal control areasizeterminal control area sizechannellogical I/O channel number for terminaltrmnalname of terminal
	Attaches a terminal to the Form Driver for processing forms over a specific, logical I/O channel, names a TCA for that terminal, and specifies the size of the TCA.
AWKSP	FDV\$AWKSP (wksp.ml.da,size.rl.r) or FDV\$AWKSP (wksp.mt.dx1,size.rl.r)
	wksp form workspace size estimate of workspace size
	Attaches a form workspace to a list of workspaces associated with the current TCA, specifies the size in bytes, and establishes that workspace as the current workspace.
BELL	FDV\$BELL
	Rings the terminal bell.
CANCL	FDV\$CANCL
	Cancels any other call presently being processed on the current terminal.

ı.

ł

)

Cali	Procedure Parameter Notation				
CDISP	FDV\$CDISP (frmnam.rt.dx1[,offset.rl.r])				
	frmnamform nameoffsetnumber controlling placement of form on screen				
	Clears the screen and displays a form. The display position may be offset fro the original form description.				
CLEAR	FDV\$CLEAR ([line[,linecnt]])				
	lineline number of first line to clearlinecntnumber of lines to clear				
	Clears the entire screen unless otherwise specified with the arguments.				
DEL	FDV\$DEL (frmnam.rt.dx1)				
	frmnam form name				
	Deletes a form from the list of memory-resident forms.				
DFKBD	FDV\$DFKBD (defkbd.rw.da,kbdnum.rl.r)				
	defkbd array of key functions and key codes kbdnum number of pairs of key functions and associated key codes defkbd array				
	Redefines the FMS keypad function keys.				
DISP	FDV\$DISP (frmnam.rt.dx1[,offset.rl.r])				
	<b>frmnam</b> form name <b>offse</b> t number controlling placement of form on screen				
	Clears the portion of the screen specified as the "clear area" in the for description and displays a form. The display position can be offset from t original form description.				
DISPW	FDV\$DISPW ([offset.rl.r])				
	offset number controlling placement of form on screen				
	Clears the portion of the screen specified as the "clear area" in the for description and displays the form that is already loaded in the workspace. T display position can be offset from the original form description.				
DPCOM	FDV\$DPCOM ([dpmode.rl.r])				
	<b>dpmode</b> value defining decimal point in signed-numeric fields				
	Defines the comma, or redefines the period, as the decimal point in fiel containing signed-numeric field-validation characters.				
DTERM	FDV\$DTERM (tca.ml.da)				
	or FDV\$DTERM (tca.mt.dx1)				
	tca terminal control area				
	Clears the terminal screen, detaches a terminal from the Form Driver, a detaches any workspaces associated with the terminal.				

Call	Procedure Parameter Notation				
DWKSP	FDV\$DWKSP (wksp.ml.da) or				
	FDV\$DWKSP (wksp.rt.dx1)				
	wksp	form workspace			
	Detaches current te	a form workspace from the list of workspaces associated with the erminal.			
GET	FDV\$GET (fldval.wt.dx1,fldtrm.wl.r,fldnam.rt.dx1[,fldidx.rl.r])				
	fldval fldtrm fldnam fldidx	field value field terminator field name field index			
	Positions and waits	Positions the cursor in the initial cursor position of a specific modifiable field and waits for the operator to enter a value.			
GETAF	FDV\$GE	TAF (fldval.wt.dx1,fldtrm.wl.r,fldnam.wt.dx1[,fldidx.wl.r])			
	fldval fldtrm fldnam fldidx	field value field terminator ending field name ending field index			
	Positions to enter a	the cursor in the current field in the form and waits for the operator value in any field.			
GETAL	FDV\$GETAL ([fldval.wt.dx1,fldtrm.wl.r[,fldnam.rt.dx1[,fldidx.rl.r]]])				
	fldval fldtrm fldnam fldidx	returned values of all fields in form field terminator starting field name starting field index			
	Positions specified able, non	the cursor in the first modifiable field in a form unless otherwise in the <b>fldnam</b> argument and allows you to enter data in all modifi- scrolled fields.			
GETDL	FDV\$GETDL (value.wt.dx1,fldtrm.wl.r[,line.rl.r[,prompt.rt.dx1]])				
	value fldtrm line	contents of data line returned from Form Driver field terminator line number on which the operator's input is displayed data line text to serve as a prompt for the operator			
	Gota a da	to line from a specified line on the screen			
GETSC	Gets a data fine from a specified fine on the screen.				
	fldnam fldval fldtrm	field name that identifies a scrolled area field values field terminator			
	Positions the specif	the cursor within the current line in the scrolled area that contains ied field and accepts input in modifiable fields within the line.			

Call	Procedure Parameter Notation		
ILTRM	FDV\$ILTRM ([trmmod.rl.r])		
	trmmod value for illegal terminator mode switch		
	Specifies the action to take when an illegal field terminator is entered. An illegal field terminator can be rejected by the Form Driver or returned to the program.		
LCHAN	FDV\$LCHAN (channel.rl.r)		
	channel I/O channel number for form library		
	Sets the channel for form library files associated with the current terminal. The Form Driver uses the specified channel for any LOPEN or LCLOS call processing.		
LCLOS	FDV\$LCLOS		
	Closes the form library associated with the current library channel for the current terminal.		
LEDOF	FDV\$LEDOF (ledno.rl.r)		
	ledno terminal LED number		
	Turns off the light-emitting diode (LED) on the VT100 keyboard.		
LEDON	FDV\$LEDON (ledno.rl.r)		
	ledno terminal LED number		
	Turns on the light-emitting diode (LED) on the VT100 keyboard.		
LOAD	FDV\$LOAD (frmnam.rt.dx1)		
	frmnam form name		
	Loads a form description into a workspace without displaying the form on the screen.		
LOPEN	FDV\$LOPEN (filspc.rt.dx1[,channel.rl.r])		
	filspcform library file specificationchannelI/O channel number for form library		
	Opens a form library and replaces the current library channel specification if the I/O channel number is supplied.		
NDISP	FDV\$NDISP		
	Marks current workspace as not displayed.		

#### Call **Procedure Parameter Notation** PFT FDV\$PFT ([fldtrm.rl.r[,fldnam.rt.dx1[,fldval.rt.dx1 [,nfldnam.wt.dx1[,nfldidx.wl.r]]]]]) fldtrm field terminator to be processed fldnam field name that identifies a scrolled area fldval field values to be displayed nfldnam current field name after call has been completed current field index after call has been completed nfldidx Processes the field terminator and checks for valid terminator codes. PUT FDV\$PUT (fldval.rt.dx1,fldnam.rt.dx1[,fldidx.rl.r]) fldval field value to be displayed fldnam field name fldidx field index Stores the value of the fldval argument and displays that value in the specified field. PUTAL FDV\$PUTAL (frmval.rt.dx1) list of field values to be displayed frmval Outputs values to all fields, stores the frmval argument values in the workspace for nonscrolled fields, and displays these values on the screen. PUTD FDV\$PUTD (fldnam.rt.dx1[,fldidx.rl.r]) fldnam field name fldidx field index Outputs the default value to a specified field. PUTDA **FDV\$PUTDA** Outputs default values to all fields in the form and displays those values on the screen. PUTL FDV\$PUTL (text.rt.dx1[,line.rl.r]) text. data line text line line number for displayed data line Outputs data to the specified line on the screen. If the line number is zero, the data line is displayed on the last line of the screen. PUTSC FDV\$PUTSC (fldnam.rt.dx1[,fldval.rt.dx1]) field name that identifies a scrolled area fldnam fldval field value Outputs data to the current line of a scrolled area that contains the specified field name.

### VAX-11 FMS Form Driver Calls

VAX-11 FMS Form Driv	ver Call	ls
----------------------	----------	----

Call	Procedur	e Parameter Notation			
READ	FDV\$READ (frmnam.rt.dx1,mloc.ml.da,mlocsiz.rl.r,frmsiz.wl.r) or				
	FDV\$RE2	AD (irmnam.rt.dx1,mloc.rt.dx1,mlocsiz.rl.r,frmsiz.wl.r)			
	frmnam mloc mlocsiz frmsiz	form name form storage area size of memory buffer that begins with <b>mloc</b> form size actually used			
	Extracts a form from the current form library, stores it in a specified memory area, and adds the name of the form to the list of memory-resident forms.				
RET	FDV\$RE2	[ (fldval.wt.dx1,fldnam.rt.dx1[,fldidx.rl.r])			
	fldval fldnam fldidx	field value field name field index			
	Returns the value for a specified field stored in the workspace.				
RETAL	FDV\$RE2	FAL (frmval.wt.dx1)			
	frmval	concatenated values of all fields except those in scrolled areas			
	Returns th workspace	ne values for all fields except those in scrolled areas stored in the $\cdot$			
RETCX	FDV\$RE1	TCX (atca.wa.r,awksp.wa.r,frmnam.wt.dx1,uarval.wt.dx1, curpos.wl.r,fldtrm.wl.r,insovr.wl.r,hlpnum.wl.r)			
	atca awksp frmnam uarval curpos fldtrm insovr hlpnum	terminal control area address form workspace address form name value of the associated text for this UAR cursor position within field returned field terminator Insert/Overstrike mode of field number of times HELP key pressed for current field			
	Returns th UAR to de	e current context of the Form Driver. You can issue this call in a termine the context in which the UAR is called.			
RETDI	FDV\$RETDI (nmdidx.rl.r,nmdval.wt.dx1[,nmdnam.wt.dx1])				
	nmdidx nmdval nmdnam	index of Named Data item text of Named Data item name of Named Data item			
	Returns th name).	e Named Data text that you specify by its index (rather than by its			

Call	Procedure Parameter Notation		
RETDN	FDV\$RETDN (nmdnam.rt.dx1,nmdval.wt.dx1[,nmdidx.rl.r])		
	nmdnam nmdval nmdidx	name of Named Data item text of Named Data item index of Named Data item	
	Returns th index).	e Named Data text that you specify by its name (rather than by its	
RETFL	FDV\$RE?	<pre>FFL (line.rl.r,value.wt.dx1,linlen.wl.r[,type.rl.r])</pre>	
	line value linlen type	line number of form to be returned value of requested line length of character string returned in value parameter type of output line requested	
	Returns th is one of th loaded but	te contents of the line that you specify with the <b>line</b> argument. This ne lines displayed by the RFRSH call. This call can also be used for undisplayed forms for report formatting.	
RETFN	FDV\$RE?	[FN (fldnam.wt.dx1[,fldidx.wl.r])	
	fldnam fldidx	field name field index	
	Returns th field is not	ne current field name and index from the current workspace. If the t indexed, the index value returned is zero.	
RETFO FDV\$RETFO (fldnum.rl.		FFO (fldnum.rl.r,fldnam.wt.dx1,fldidx.wl.r)	
	fldnum fldnam fldidx	field number field name corresponding to <b>fldnum</b> field index corresponding to <b>fldnum</b>	
	Returns th	ne name and index of the nth field in the form.	
RETLE	TLE FDV\$RETLE (fldlen.wl.r,fldnam.rt.dx1[,fldidx.rl.r])		
	fldlen fldnam fldidx	field length excluding field-marker characters field name field index	
	Returns th	e number of data characters in the specified field.	
RFRSH	FDV\$RFI	RSH	
	Refreshes pressing tl	the screen. The RFRSH operation is identical to that initiated by he CTRL/R keys.	
SIGOP	FDV\$SIG	OP	
	Causes the	e application program to signal the operator.	
SPADA	FDV\$SPADA (mode.rl.r)		
	mode	numeric/application keypad mode	
	Sets the k	eypad to numeric or application mode.	

Call	Procedure Parameter Notation			
SPOFF	FDV\$SPOFF			
	Turns supervisor-only mode off for the current terminal, allowing the opera- tor to modify fields protected with the Supervisor Only attribute.			
SPON	FDV\$SPON			
	Turns supervisor-only mode on for the current terminal, treating fields pro- tected with the Supervisor-Only attribute as display-only fields.			
SSIGQ	FDV\$SSIGQ (sigmd.rl.r)			
	sigmd bell/reverse video signaling mode			
	Sets signal mode for the current terminal. Audio mode (0) rings the terminal bell. Video mode (1) reverses the VT100 video image.			
SSRV	FDV\$SSRV ([status.wl.r[,iostat.wl.r]])			
	statusgeneral status reporting variableiostatI/O status reporting variable			
	Sets the addresses of the status reporting variables.			
STAT	FDV\$STAT (status.wl.r[,iostat.wl.r])			
	statusgeneral status codeiostatI/O status code			
	Returns the status code for the last Form Driver call.			
STERM	FDV\$STERM (tca.ml.da)			
	or FDV\$STERM (tca.rt.dx1)			
	tca terminal control area			
	Sets current terminal and the workspace most recently associated with that terminal to the current workspace. The TCA must have been previously at- tached by the FDV\$ATERM call.			
STIME	FDV\$STIME (time.rl.r)			
	time timeout period in seconds			
	Specifies the number of seconds the Form Driver waits for operator response to a GET-type call.			
SWKSP	FDV\$SWKSP (wksp.ml.da) or FDV\$SWKSP (wksp.mt.dx1)			
	wksp form workspace			
	Specifies the workspace that the Form Driver uses for the current workspace. The workspace must have been previously attached by the FDV\$ATERM call.			

Call	Procedure Parameter Notation		
TCHAN	FDV\$TCHAN (channel.rl.r)		
	channel physical I/O channel number for terminal		
	Changes the terminal channel associated with the current TCA to the speci- fied value.		
WAIT	FDV\$WAIT ([fldtrm.wl.r])		
	fldtrm field terminator code		
	Causes the application program to wait until the operator presses the ENTER key. This call allows the Form Driver to set the application program to the operator's pace.		

# Appendix B. Sample Application Program Form Descriptions

The FMS Sample Application program uses thirteen forms. The form descriptions and their screen images are presented in this appendix. The descriptions are written in the Form Language. The *VAX-11 FMS Utilities Reference Manual* describes the Form Language in detail.

Understanding the forms can help you understand the sample program. Refer to the form descriptions and their screen images as you review the Sample Application program. Some of the screen images in this appendix are not equivalent to their form description, because the images include data supplied by the Sample Application program.

The form descriptions and their screen images appear in the following order:

- ACCOUNT\_DATA
- CHECK
- CHECK DONE
- DEPOSIT
- HELP\_ACCOUNT\_DATA
- HELP\_CHECK
- HELP\_DEPOSIT
- HELP\_KEYS
- HELP\_MENU
- HELP\_WELCOME
- MENU
- REGISTER
- WELCOME

#### Help for Viewing the Account Data

You can view the account data at any time. If you know the secret password, you can change the records--everything but the account number and the date the account was opened.

If you wish to change any account data, enter the secret password and then press RETURN. If you do not give the correct password, you will be returned to the menu.

If the password is accepted, you can change any of the name, address, or phone fields. When you press RETURN (even if you are not in the last field), your changes take effect for the rest of the session. However, they are not made permanently in the SAMP file. (This is, after all, only a simple sample application.) If you press keypad period at any time, no changes are made and you are returned to the menu.

You can return to the menu by pressing RETURN.

For more help, press HELP. To continue, press RETURN.

#### Help for Writing a Check

You can write checks up to your current balance, which is always at the bottom of the screen. Just fill in the payee, the amount to pay, and, if you like, what the check is for. Use the TAB and BACKSPACE keys to move between fields.

The amount will be accepted if it is covered by the balance. The payee and memo will always be accepted.

After you are satisfied with the amount, payee, and memo, press RETURN. The check is recorded in your check register, and the account's balance is updated.

Stop the program at any time by pressing keypad period. Any check partially entered will be voided. It will not be entered in your register.

After writing a check, you will be given the option of putting a copy of the check into a check file (SAMPCH.DAT) for later printing. You can then write another check or return to the menu.

#### Help for FMB and SAME Control Keya

IL uses some	standard editing keys. They are:
RETURN	Signifies that you are done with a form.
TĀB	Noves cursor to the next field.
BACKSPACE	Moves cursor to the previous field.
DELETE	Deletes the character to the left of the cursor.
LINEFEED	Deletes the contents of an entire field.
Other FNS ke	ys are:
LEFTARRON	Noves cursor back in a field.
RICHTARROW	Noves cursor forward in a field.
CTRL/R	Refreshes the screen.

also defines some keys. At any time while running SAMP, you can press keypad period to stop what you are doing and return to the menu.

Other keys are defined by SAMP at different points in the application. Use of these keys will be noted as you progress through the program.

To continue, press RETURN.

Help for SAMP Menu

SAMP simulates some functions of electronic banking. In this application you can make deposits and write checks at your terminal.

Your account at this bank has already been set up. You have made several deposits and have written some checks. When SAMP starts, you are able to request the following functions by typing the number and then pressing RETURN. You can stop SAMP by typing 1 or by pressing keypad period.

1 EXEL To leave SAMP and return to operating system level.

2 write a wheel? You are asked to fill in payee, amount, and meno information.

3 Make successful You are asked to fill in the amount and meno information.

4 Fiew cherk register You can review checks and deposits made in the past.

5 Show success as a You can see the data associated with your account.

For more help, press HELP. To continue, press RETURN.

Help for the FMS V2 Sample Application Program

The FMS Sample Application program (SAMP) serves two purposes:

- 1. It tests the Form Driver and is part of the Installation Verification Procedure.
- It shows how to use FMS. The Sample Application is available in each language supported by FMS, and the documentation cites many examples that are from SAMP.

The application does not claim to show the <u>best</u> way of doing everything. Rather, it shows ways that things <u>can</u> be done with FMS.

As you run the rest of SAMP, you can get help by pressing the PF2 key, which will be referred to as the HELP key. Repeated pressing of the key provides additional help until the message is displayed, "No help available." If you press HELP now, you will see an explanation of the keys used in FMS.
